

BASELINE BIOPHYSICAL INFORMATION ABOUT THE TULANG BAWANG WATERSHED AREA, NORTH LAMPUNG

Afandi¹, Abdul Gafur¹, I Gede Swibawa¹, and Pratiknyo Purnomasidhi²

¹ College of Agriculture, University of Lampung
Bandar Lampung 35145, Indonesia and

² International Center for Research in Agroforestry (ICRAF) South East Asia
Bogor 16001, Indonesia

EXPERIMENT SITES

The proposed experiment sites are located in the Tulang Bawang watershed, Lampung Province, which is situated in the southern part of Sumatera Island (Figure 1). As shown in Figure 1, at present three locations of experimental units are available, i.e. Krui (ICRAF), Sumber Jaya (University of Lampung) and Ketapang (ASB, BMSF).

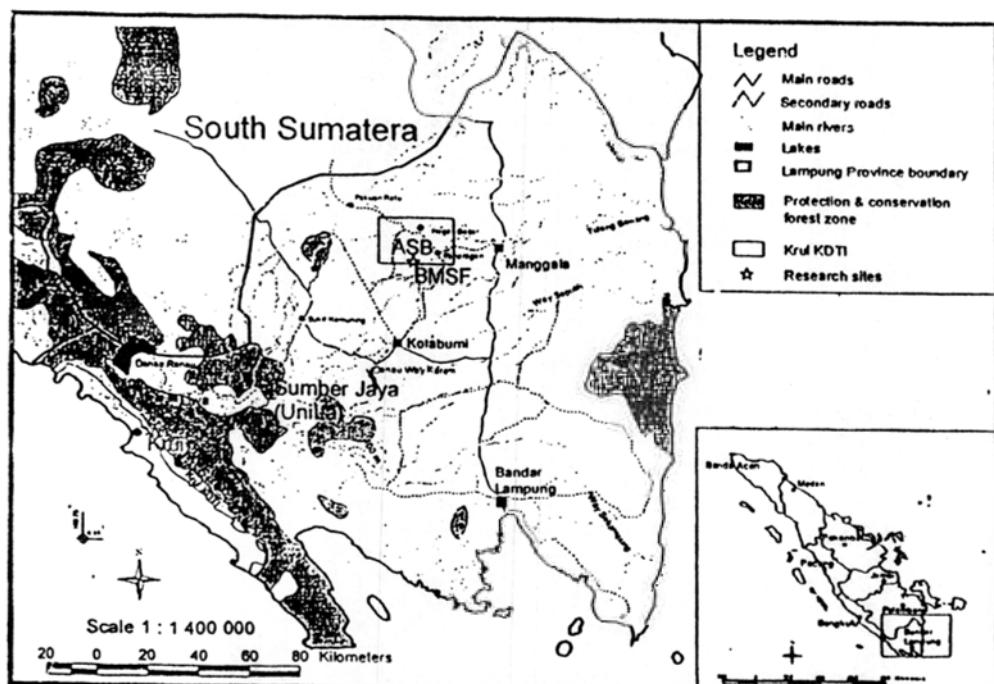

Figure Location map of experiment sites.

CLIMATIC SITUATION

Regional

Rainfall in Lampung region is controlled by the monsoonal system comprising two monsoon seasons each year. In general terms the temporal variation of rainfall may be characterized by two seasons, i.e. wet season lasting from November to about May which is followed by dry season from June to October.

Oldeman *et al.* (1979) made an agroclimatic zone for Lampung and South Sumatra based on the following definitions: (a) a wet month has a long term average rainfall of 200 mm or more, (b) a dry month has a long term average rainfall of 100 mm or less. Based on that criteria, Lampung region was dominated by four agroclimatic zones, i.e (a) Zone A (more than 9 wet month) is found along the southeast coast, (b) Zone B1 (7-9 wet months) is found east of the watershed of Bukit Barisan, (c) Zone C1 (5-6 wet months and less than two dry months) occurs along the Souht cost and at the centre of Lampung region, and (d) Zone C2 (5-6 wet months and 2-3 dry month)s is found at the eastern part on this region (Figure 2).

Local

As reported by Binnie and Partners (1994a), the mean annual rainfall of Tulang Bawang subwatershed is around 2700 mm in the central part of the basin, but reduces to values below 2500 mm in the low lying eastern part as well as in its north western corner. The isohyetal map of the basin is shown in Figure 3. Utomo *et al.*(1999) reported the local climate of Way Besai catchment which at the upper Tulang Bawang watershed (Tables 1-5).

SOIL TYPES

Regional

Based on national soil classification (Centre for Soil Research, 1983), four main soil types were found along the Tulang Bawang Basin, i.e. Latosol, Podzolic, Alluvial, and Gleysol (Binnie and Partners, 1994b). In the FAO or USDA soil taxonomy system, the soils have the following names (Table 6).

Latosol was usually found at the upper watershed, in the hilly areas. The Latosol was characterized by deep, uniform, friable, red or brown clays derived from volcanic materials of basic-intermediate composition. This soil was cultivated by the indigenous people with coffee, pepper, cloves, and dryland arable crops. Podzolic is the largest soil type found in the Tulang Bawang watershed, usually situated in peneplain areas. The Podzolic soils are derived from acid tuffs and sedimentary rocks, and characterized by sandy surface soils overlying a poorly structured clayey subsoil, with both the physical and chemical properties are

inferior. Alluvial and Gleysol are found at the lower part of the basin. Alluvial soils are young soils, and generally slightly better drained than Gleysol. Some chemical soil properties from several sites in Tulang Bawang watershed were shown in Table 7.

Local

Tim Studi Universitas Lampung (1982) found two soil types at Way Besai subwatershed, i.e. Brown Podzolic (Orthic Acrisols/Typic Tropudults) and Red Yellow Podzolic (Orthic Acrisol/Typic Tropudults/Typic Dystropepts). The areas are occupied by the Brwon Podzolic (66,9%), the rest (33,1%) is occupied by the Red Yellow Podzolic. Salam *et al.* (1998) reported some of the soil properties in the Way Besai subwatershed (Table 8).

WATER RESOURCES

Regional

The province of Lampung comprises five big rivers and about 25 smaller ones forming eight watersheds with five watersheds, Mesuji, Tulang Bawang, Seputih, Sekampung and Way Semangka, as the main ones. About 80 % of the rivers flow to the east side ending in Java Sea (Mesuji, Tulang Bawang, Seputih, and Sekampung) and Teluk Semangka (Way Semangka) (Wiryawan *et al.*, 1999). The size of catchment and discharge of the main rivers is presented in Table 9.

Local

Binnie and Partners (1994a) reported that the mean annual runoff within the Tulang Bawang watershed is within the range of 1100-2300 mm/year, which clearly displays the joint effects of rainfall and evapotranspiration. Utomo *et al.* (1999) reported the mean monthly flow of Way Besai River as shown in Table 10. Using data in table, Sinukaban *et al.* (1999) reporeted that the total water yield of the cathment is 20.2 m³/s or 650 million m³/year, about 63.7% of the average annual rainfall. The maximum monthly stream flow is in March and the minimum occurs in September.

TOPOGRAPHY

Regional

The topography of Lampung region is shown in Figure 4. Most of the Lampung region is dominated by peneplain areas with the slope gradient of 0-15%. The hilly and mountainous areas are situated in the west part of Lampung province which belongs to the Bukit Barisan mountain range. According to Wiryawan *et al.* (1999) the topographic unit of Lampung region can be devided into five categories:

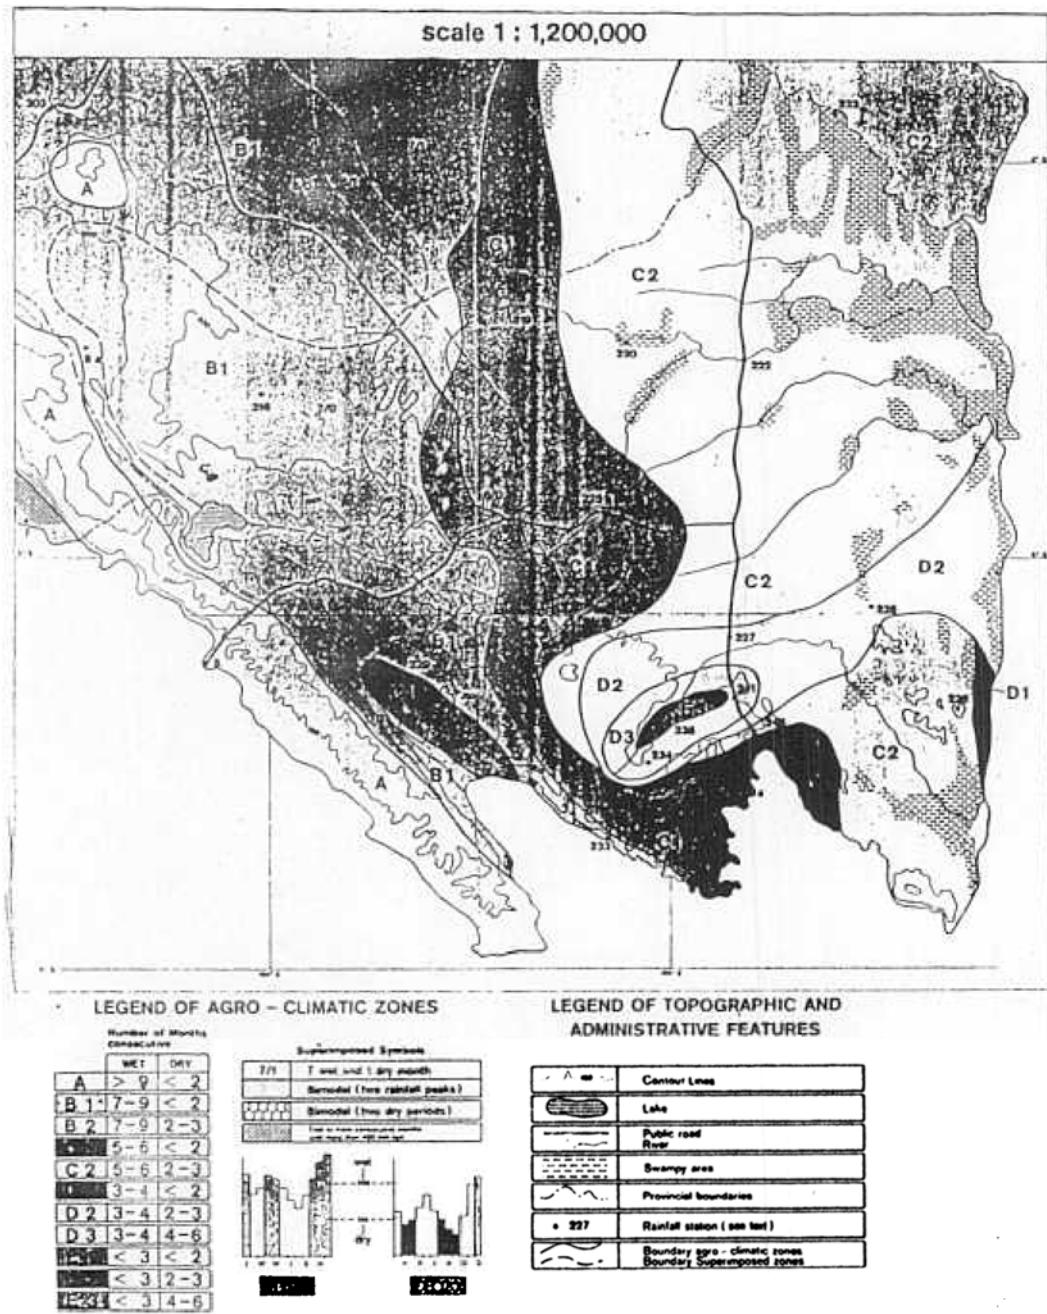

Figure 2. Agroclimate map of Lampung and South Sumatera (Oldeman *et al.*, 1979).

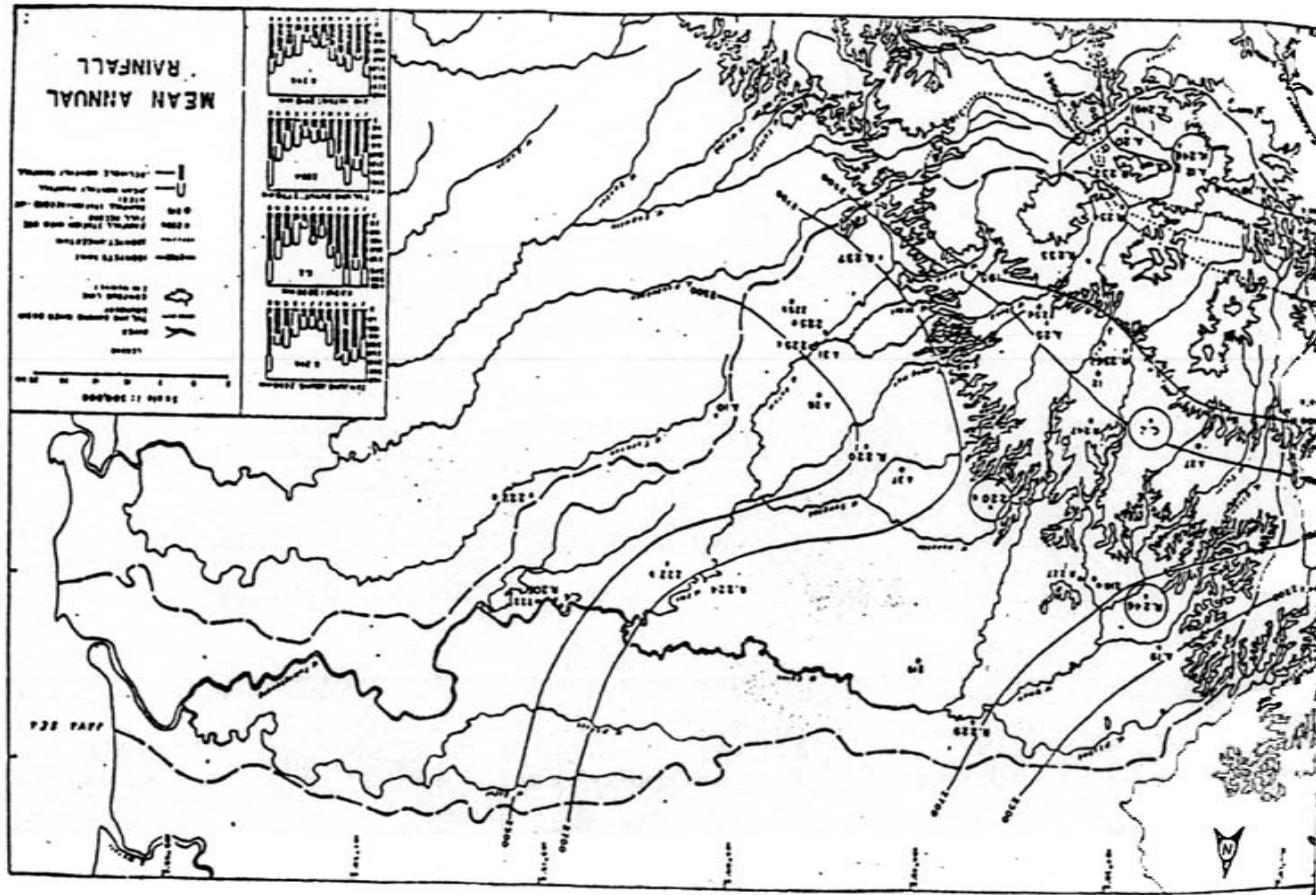

Figure 3. Isohyetal map of the Tulang Bawang watershed (Binnie and Partners, 1994a).
